

“*P. stirpe filiformi, rachi distiche pennata : pinnis lunatis remotis alternis;*” and the habitat “*in O. Norvegico,*” seems to confirm the reference.

Virgularia differs from Pennatula remarkably in this that no spicula enter into the composition of its soft parts. The polypiferous pinnules are secund, leaving the posterior part naked, and this is marked with a deep furrow extending from one end to the other, dividing the polypidom into two symmetrical halves.
