tion confined to the higher classes of animals. The wonderful powers of flight possessed by many insects, enable them to travel over an immense extent of country. The Locust and the Ant tribe are familiar examples. These insects occasionally migrate in countless swarms from the lands to which they are indigenous, and lay waste others far remote.

Equally remarkable is that habit of animals termed Hybernation. Like the plants of temperate climates, some animals have the faculty of passing the colder season of the year in a state of sleep. The Hedgehog and the Dormouse may be mentioned as examples of quadrupeds possessing this faculty. Additional instances might be given in all the classes of animals. Nearly allied to Hybernation, is that remarkable instinct which guides many of the inferior animals to deposit their eggs in the earth, or in some other place of safety; that they may be preserved during the season of diminished temperature. This instinct is particularly observable in insects whose lives are ephemeral, or are, at the utmost, prolonged for a summer.

There is yet another circumstance that remains to be noticed, as being connected with the adaptation of animals to the climates in which they live; namely, the *Clothing* or covering with which animals have been supplied by
